COURSE CURRICULUM

Storefront Masterclass

Build a web and mobile storefront where sellers open a store, list items and get paid. Guests can buy without an account.

Next.js 15 · Supabase · Paystack · Resend · Capacitor · Vercel · GitHub Actions

10 MODULES one video each · ● Noah 1, 2, 4, 5, 9 ○ Co-founder 3, 6, 7, 8, 10

	MODULE	WHAT GETS BUILT	OWNER	END STATE
01	**Setup, Supabase & Keeping Secrets Safe**	Repo, Next.js app (static export), Supabase project, tables (stores, products, orders, order_items), Row Level Security, .env.local and Vercel env vars, buy the domain and verify it with Resend, set up Claude safely with SQL migrations on a dev project	● Noah	Empty app talking to a secured database; domain and email ready; no secrets in the repo
02	**Seller Accounts & Store Creation**	Supabase Auth, store profile, add and edit products with image upload	● Noah	A seller can sign up and list an item
03	**Storefront, Cart & Guest Checkout**	Public store page, product listing, cart state, checkout with no login, account prompt only at the pay step	○ Co-founder	A guest can fill a cart and reach checkout
04	**Payments & Orders**	Paystack checkout, Edge Function webhook to verify payment, order saved as paid, seller sees orders	● Noah	A test-mode payment creates a paid order
05	**Email Verification & Notifications**	Email verification code at checkout, order confirmation and receipt emails to the buyer, new-order emails to the seller (Resend)	● Noah	A sale triggers emails to buyer and seller
06	**Wrap the Web App with Capacitor (Android)**	Add Capacitor, build the Android app, run it on a device	○ Co-founder	App runs on a real Android phone
07	**Native Features & iOS**	Push notifications (FCM), splash screen and icons, deep links, iOS build and TestFlight	○ Co-founder	A sale sends a push to the seller's phone
08	**CI/CD with GitHub Actions**	Lint, test and build on every push, Android build artifact, Vercel deploy, secrets handling	○ Co-founder	Push to main deploys the web app and builds the APK
09	**Vercel Production Launch**	Attach the domain to Vercel, production env vars, switch Paystack to live, Supabase production settings	● Noah	Live on the real domain
10	**Onboarding Assessment & Go-Live**	Students sign up on the live app and complete the assessment; Terms and Privacy published	○ Co-founder	Students onboarded on the MVP

KEY HANDLING RULES taught in Module 1

Assume the app bundle is public. Anything prefixed NEXT_PUBLIC_ is bundled into the website and the APK. Only three values ship in the app: the Supabase URL, the Supabase anon key and the API URL.

The anon key is safe because of Row Level Security. Plain reads and writes (products, cart, store profile) go straight to Supabase.

Sensitive actions go through Edge Functions. Create order, verify payment and send email run in Supabase Edge Functions that check the user's login token. Allow the Capacitor origins (https://localhost, capacitor://localhost) in CORS.

Secrets live only in Edge Function secrets. The service-role key, Paystack secret key and Resend key are set with supabase secrets set. They never go in the app, the repo or Vercel.

Local and Vercel setup. Public values go in .env.local (gitignored) with a blank .env.example committed, and the same public values go in Vercel environment variables.

Claude and the database. Claude writes SQL migrations applied with the Supabase CLI against a separate dev project. It never gets the service-role key, and a deny rule stops it reading .env files.

Safety nets. GitHub push protection and secret scanning. If a key leaks, rotate it in the dashboard immediately.

DECISIONS AND RISKS TO SETTLE BEFORE RECORDING

Resend free tier

Notes say about 300 emails a month. I believe the free plan is higher (about 3,000 a month, 100 a day). Confirm on their pricing page.

iOS

Needs a Mac and a paid Apple Developer account (about $99 a year). Say so up front.

Static export

No server-rendered pages. Use client-side routing for stores and products, and put webhooks in Edge Functions.

Android build tools

An APK still needs the Android SDK. GitHub Actions can build it for students (Module 8), but Module 6 needs Android Studio or the SDK locally.

Paystack

Test mode covers Modules 4 to 8. Going live needs business verification, so start early. Decide how sellers get paid (split payments or subaccounts) before Module 4.

Seller dashboard

Kept to an orders list to stay at 10 modules. Anything bigger is a bonus module.
